

## INFORMATICS

### **Problems of cryptographic primitives implementations in network protocols.**

supervisor: doc. RNDr. Jozef Jirásek, PhD. (jozef.jirasek@upjs.sk)

study from: full time/external

Annotation: Nowadays, secure internet protocols are using several cryptographic primitives at the same time in different combinations and in different modes. Even though the individual primitives are subject to many security analyzes, their current use can lead to further unexpected vulnerabilities. The work will analyze the possibilities of parallel attacks on the primitives, used cryptographic functions and the methods of their use with the intention of proving the feasibility of specific safety objectives, or propose protection against identified vulnerabilities.

### **Plasticity and attention in spatial hearing.**

supervisor: doc. Ing. Norbert Kopčo, PhD. (norbert.kopco@upjs.sk)

study form: full time

Annotation: In everyday situations, humans are exposed to multiple concurrent stimuli in complex, continuously changing environments. To correctly extract relevant information, they adapt their processing to reflect the specifics of the current scene, and they learn from previous experience to improve the perceptual strategies used. The current project proposes to perform a series of behavioral experiments, brain imaging studies, and computational modeling to study how attention and mechanisms of implicit and explicit learning are used to cope with complex listening environments for speech processing, sound localization, and learning of new phonetic categories.

### **Cross-modal interactions and spatial auditory processing.**

supervisor: doc. Ing. Norbert Kopčo, PhD. (norbert.kopco@upjs.sk)

study form: full time

Annotation: Vision influences how we perceive space by hearing. Ventriloquism effect and after-effect are phenomena illustrating short-term plasticity in spatial hearing induced by visual signals. Visual attentional cuing also influences spatial auditory processing both in terms of sound localization and spatial benefit in speech perception. The current project will examine the effect of visual information on spatial auditory perception by performing behavioral experiments, neuroimaging studies, and computational modeling.

### **Brain-training games for spatial hearing.**

supervisor: doc. Ing. Norbert Kopčo, PhD. (norbert.kopco@upjs.sk)

study form: full time

Annotation: Solutions designed to enhance auditory processing when hearing thresholds are within normal limits are very limited and none are as recognized or as widely available as are hearing aids and cochlear implants. The project aims to contribute to the development of novel procedures to rehabilitate auditory processing deficits (APD) by developing a brain training game based on modern auditory neuroscience and the results of the EU Horizon 2020 ALT grant. The development of auditory brain training game will be in collaboration with University of California, Riverside Brain Game Center and Oregon Health State University. The main goal of

the games is to develop and test rehabilitative techniques that restore auditory function for those who perform poorly on tests of APD by training various aspects of auditory processing.

### **Formal concept analysis.**

supervisor: prof. RNDr. Stanislav Krajči, PhD. (stanislav.krajci@upjs.sk)

study form: full time/external

Annotation: Formal concept analysis is a data-mining method applied to a rectangular matrix of data in which each row corresponds to some object, each column corresponds to some possible attribute, and the matrix field value denotes a membership of the column attribute for row object. One of the goals of this method is to find so-called concepts, which are stable (in some sense) pairs of subsets of objects and attributes. The method can be considered a nice application of the algebraic notion of a Galois connection. It has been described in detail by Ganter and Wille, in particular for the so-called crisp case with binary matrix data. A natural question that arises is what happens if the matrix data are non-binary...

### **Graph theoretical and algorithmic aspects of communication networks.**

supervisor: prof. RNDr. Gabriel Semanišin, PhD. (gabriel.semanisin@upjs.sk)

study form: full time

Annotation: The development of Internet of Things requires solutions for various aspects of a communication in computer and sensor networks. These networks can be modelled by graph-theoretical concepts. Such models provide bases for a formulation and solution of algorithmic problems that are related to network creation, data transfer and securing. These topics are studied very extensively and relatively big number of recent papers with significant theoretical and practical impact was published recently.

### **Analysis of sensor data using machine learning methods.**

supervisor: prof. RNDr. Gabriel Semanišin, PhD. (gabriel.semanisin@upjs.sk)

consultant: RNDr. Ľubomír Antoni, PhD.

study form: full time

Annotation: Data analysis solutions are applied in various areas of technical, natural, human and economic sciences. Machine learning is a sub-area of artificial intelligence that deals with machine learning methods and algorithms based on input data in a defined solution space. The aim of the dissertation thesis is to design and application of algorithms and methods of machine learning in case studies of sensor data analysis and to compare the performance of the proposed solution with other available studies.

### **Analysis of digital evidence using machine learning methods**

supervisor: prof. RNDr. Gabriel Semanišin, PhD. (gabriel.semanisin@upjs.sk)

consultant: RNDr. JUDr. Pavol Sokol, PhD.

study form: full time

Annotation: Digital forensic analysis has become an essential part of responding to cybersecurity incidents as well as part of cybercrime investigation. An important phase

of forensic investigation is the analysis of digital evidence itself. Within this phase, it is necessary to extract forensic artefacts, determine their relevance, value for the case, as well as relationships between them. The purpose of this phase is to confirm, resp. reject the forensic hypotheses established in the early stages of the forensic investigation. The aim of this work is to analyze the possibilities of using machine learning methods in the analysis of digital tracks with respect to the complexity, volume, and heterogeneity of forensic artefacts. At the same time, the aim is to propose a method of selection for the case of relevant forensic artefacts, to find a relationship between them as well as to verify the forensic hypothesis itself.

### **Forensic analysis of the internet of things.**

supervisor: prof. RNDr. Gabriel Semanišin, PhD. (gabriel.semanisin@upjs.sk)

consultant: RNDr. JUDr. Pavol Sokol, PhD.

study form: full time/external

Annotation: The Internet of Things (IoT) is becoming an integral part of everyday life. Also, it brings a significant increase in security threats and security incidents. An important aspect of the investigation of computer security incidents is an adequate forensic investigation. Within this investigation, several problems can be identified that are related to the heterogeneity of the available IoT-producing components. The aim of the work is to analyze the possibilities of using machine learning methods in securing, extraction and analysis of digital tracks from these devices as well as to design an automated method of extraction and analysis of forensic artefacts from IoT components.

### **Modeling and algorithms for construction of smooth curves.**

supervisor: doc. RNDr. Csaba Török, CSc. (csaba.torok@upjs.sk)

study form: full time

Annotation: Recently we proposed a new approach to solving the tridiagonal systems on a uniform grid of nodes. One of the goals of the thesis is to investigate the effect of the given approach on the nonuniform grid and the inversion of tridiagonal matrices. Classic cubic splines of class  $C^2$  are implicit. We succeeded to express them in an explicit form that enables a design of a linear model for approximation and estimate of spline coefficients. The second goal is to analyze the properties of LS estimate of coefficients and their comparison with B-splines. The third goal is finding of criterion of optimal stopping in on-line approximation according to prediction in an appropriate metric.

### **Shannon's sampling theorem and real problems.**

supervisor: doc. RNDr. Csaba Török, CSc. (csaba.torok@upjs.sk)

study form: full time

Annotation: The sinc function based sampling theorem provides sufficient conditions to guarantee that infinite discrete sequences capture all the information from the continuous signal and thus enables the full reconstruction of the original one. Thanks to it, it is possible to develop various geometric, physical or numerical models for practice. However, observed signals, sequences of real records or simulated and calculated data are final, and practice has shown that for their effective description, interpolation, approximation or analysis it is insufficient to consider only sinc functions,

especially in the case of uniform nodes. The question is how to design the models so that they can be used effectively in applications and give the most accurate results.

### **Attacks on machine learning methods in the field of cybersecurity.**

supervisor: doc. RNDr. Csaba Török, CSc. (csaba.torok@upjs.sk)

consultant: RNDr. JUDr. Pavol Sokol, PhD.

study form: full time

Annotation: Machine learning methods play an essential role in responding to security incidents. To detect security incidents, respectively security attacks, these methods make training data models of normal behaviour and detect incidents, respectively attacks as deviations from these models. This process encourages the attackers to manipulate training data in such a way that the learned model cannot detect their subsequent attacks. In addition to the learning phase, security systems using machine learning methods are also vulnerable to various attacks during the decision-making phase. Using specially selected inputs, the attacker bypasses the learned behaviour of the detection system. This work aims to analyze used machine learning methods in the field of cybersecurity concerning their resistance to the above attacks. At the same time, the aim is to propose a method of testing machine learning methods with regard to the possibility of their misuse by the attacker and how to protect these methods against various types of attacks.

### **Intercontext structures and information preserving.**

supervisor: doc. RNDr. Ondrej Krídlo, PhD. (ondrej.krislo@upjs.sk)

study form: full time

Annotation: Formal Concept Analysis (FCA) provides tools for extracting implicit knowledge from any tabular data. The challenge of this dissertation should be research in the environment of interconnecting multiple tables while maintaining the internal structural and knowledge properties of the input data. The FCA has had theoretical tools for this since its inception, but it does not take into account the semantic side of this problem. But the latest results coming from our institute pave the way which one can find out. It's still just the beginning. The output of this dissertation should be a continuation, whether from a theoretical or algorithmic point of view, they also needed a considerable amount of experimentation with various real data.
